5. Telamona salvini.

*Telamona salvini*, Dist. Ent. Monthly Mag. xvi. p. 11 (1879) ¹

**Hab.** GUATEMALA, Chinantla 4100 feet (*Salvin ¹*), Guatemala city (*Champion*).

The specimens from the two localities differ somewhat *inter se*, and may belong to two different species. The insect is distinguished by the truncate dorsal process; it is very closely allied to *T. spretata*, Goding, and is perhaps not really distinct from it. The latter species has the dorsal protuberance broadly and evenly truncate as in *T. salvini*, but it is set further back from the metepidium and has the two apical angles rounded; in *T. salvini* the hinder angle is sharp and somewhat produced, and the front angle is more broadly rounded.

The colour of this species, like that of the other members of the genus, is variable; the pronotum in the type specimen is almost unicolorous brown, with darker markings behind, whereas in the example from Guatemala city it is much mottled with griseous and fuscous-brown.

6. Telamona albidorsata, sp. n. (Tab. IX. figg. 8, 8 a.)

*Fusco-picea, nitida, pronoto fortiiter, postice rugosius, punctato, ad latera maculis minutis albidis irrorato et dorso fere ab apice protuberantiam ad apicem posticum sat late albido, illa elevata, simplici, vix porrecta, apice rotundato, antice abrupte in metepidium situatim declivi, postice lenius in processum posticum mergentem, apice hujus negro, humeris obtusis, leviter prominulis; tegminibus apicem prortocarci superantibus, parte apicali infuscatâ; pedibus piceo-testaceis.*

Of a fuseous colour, with the pronotum furnished with a broad and distinct white or greenish-white band along its whole upper ridge from near the apex of the dorsal protuberance to the apex of the posterior process; the sides, too, are irrorated with small spots of the same colour; the dorsal protuberance is simple, slightly porrect, rounded at the apex, abruptly and with a very slight situatum declivous in front, and behind merging with a strong and even sweep into the posterior process, with which it forms a very obtuse and hardly perceptible angle behind the middle; tegmina fusco-hyaline, clearer on the external margin and broadly infuscate at the apex; legs pitchy testaceous.

**Long.** 9 ¹⁄₄ millim.; lat. int. hum. 4 ¹⁄₂ millim.

**Hab.** MEXICO, Rinconada in Vera Cruz (*Schaus*).

One male specimen.

7. Telamona satyrus, sp. n. (Tab. IX. figg. 9, 9 a.)

*Brunnia, piceo griseoque variegata, capite leviter, pronoto sat fortiiter punctato, postice rugoso; humeris ut in specie precedenti valde prominentibus, auritus; protuberantia dorsali simplici, haud truncata, apice rotundato, in metepidium sat abrupte declivi, postice ad basal fortiiter impresso et situato in processum posticum mergente; tegminibus hyalinis ad apicem et interdum in medio bruneis; pedibus testaceis, tarsiis infuscatis.*

A rather large species, of a brown colour, variegated with fuscous and griseous; pronotum strongly punctured, with traces of rugose raised lines at the sides; shoulders strongly prominent, auriculate; dorsal protuberance nasute, rounded and slightly deflexed at the apex, with a deep and strong, though small impression on each side at the base; the dorsum, if viewed from the side, extends in a broad situatum into the posterior process, which is long and nearly reaches the apex of the tegmina; the latter are hyaline, with the apex at least brown or smoky; legs testaceous, with the tarsi infuscate.

**Long.** 10 ¹⁄₂-11 millim.; lat. int. hum. 7 millim.
