

the third, the latter a little shorter than the fourth; the remaining joints very closely united. Head sparsely covered with a white pubescence; the face coarsely, transversely, rugosely punctured, and with a Λ -shaped (not very clearly separated) raised part in the centre; the cheeks more closely and much less strongly punctured; front and vertex shining, sparsely covered with shallow, moderately large punctures; the vertex raised in the centre; the eyes slightly diverging and clearly margined. Thorax above bearing separated punctures like those upon the head; the metanotum more closely punctured, shining; pleuræ punctured, the punctures running into reticulations; the sutures striated and shining; the lower part of the mesopleura shining and impunctate. Petiole shining, longitudinally striolated above. Legs stout, the hind tibiæ and tarsi densely covered with a whitish (not bristly) pile. The metatarsus is as long as the following three joints united; the spurs pale, the longer one reaching to the middle of the metatarsus. All the knees are pale; the four anterior tibiæ and tarsi are pale reddish-testaceous. The scape beneath is pale reddish; the mandibles are red, black at the tips.

E. guatemalensis is separated from the other species of this group from our region by the thorax not being rugosely punctured.

Fam. TRIGONALIDÆ.

A remarkable family, containing comparatively few species, but having a wide range over the globe. By some authors its only genus is placed among the Evaniidæ; but it does not appear to me to have a very near relationship with *Evania*.
